

Plant endophytes

Here fungi enter the scene

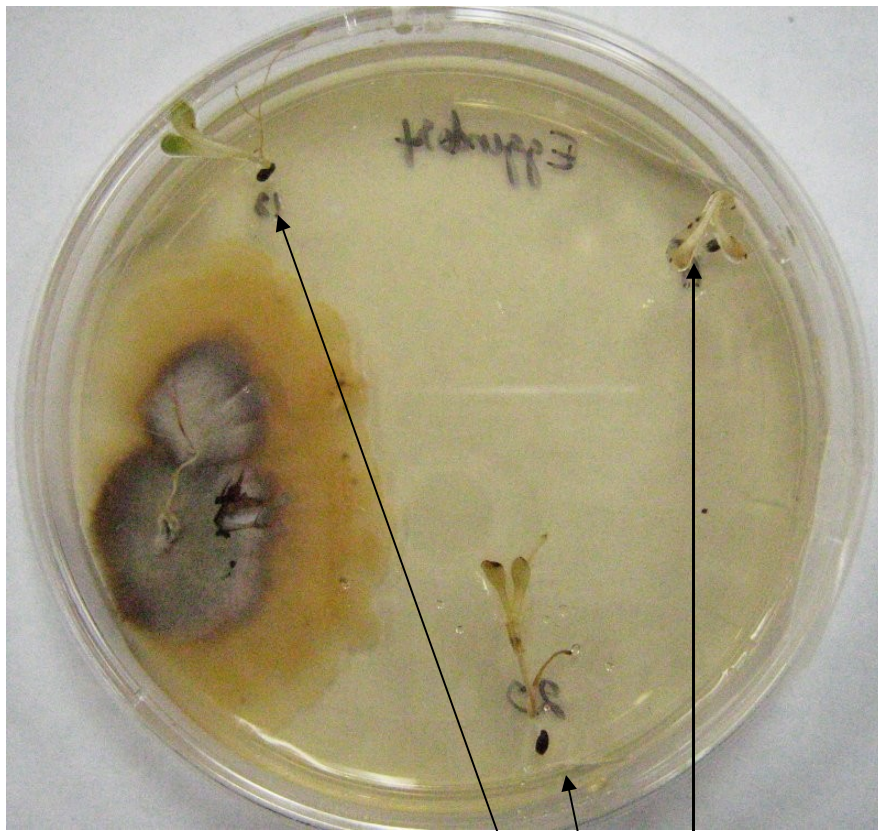

Fungal endophytes:

- 1) Inhabit every plant;
- 2) Produce many chemicals solely or in the interaction with host plant;
- 3) Have full spectrum from parasitism to commensalism (but most of them are not parasites — Ganley, Brunsfeld & Newcombe, 2004).

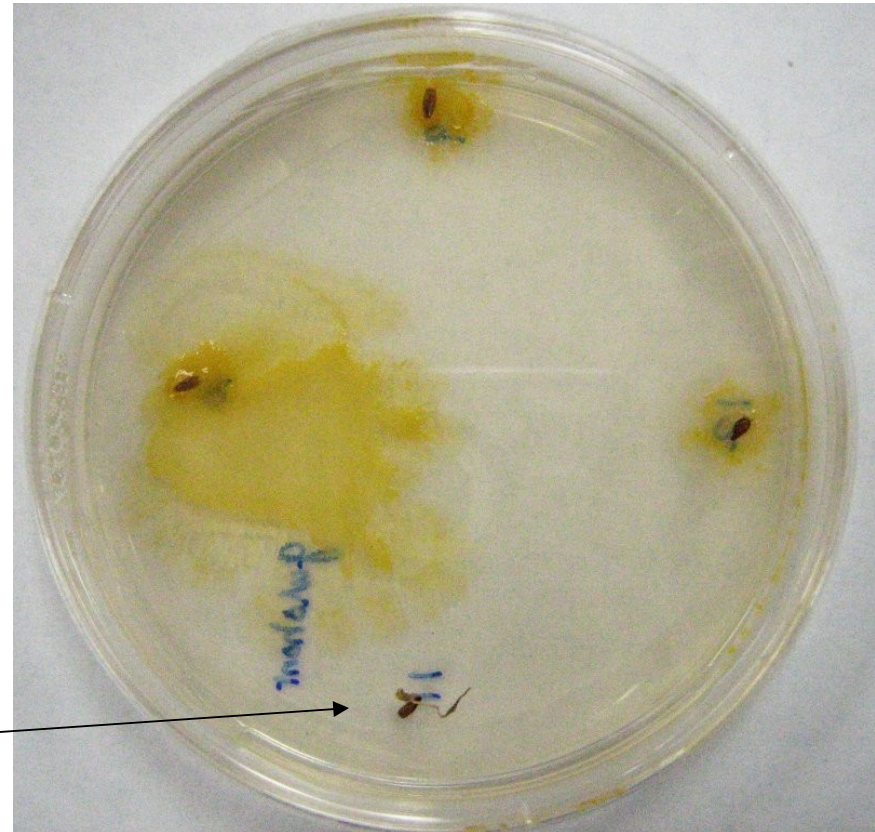

Are endophytes involved in the creation of “weed of mass destruction”?

Isolation

Endophytes are usually isolated from the achenes of knapweed

endophyte-free achenes

Endophyte-free plants

Plants from natural habitats are usually rich of endophytes (70%–90% of seeds). If vertical transmission accounted for the presence of endophytes in seeds of surveyed plants, then infected plants would produce seeds from which we would isolate endophytes at field incidence. This is not the case: seeds have been free of endophytes.

Competition experiment

E+
knapwe
ed and
fescue

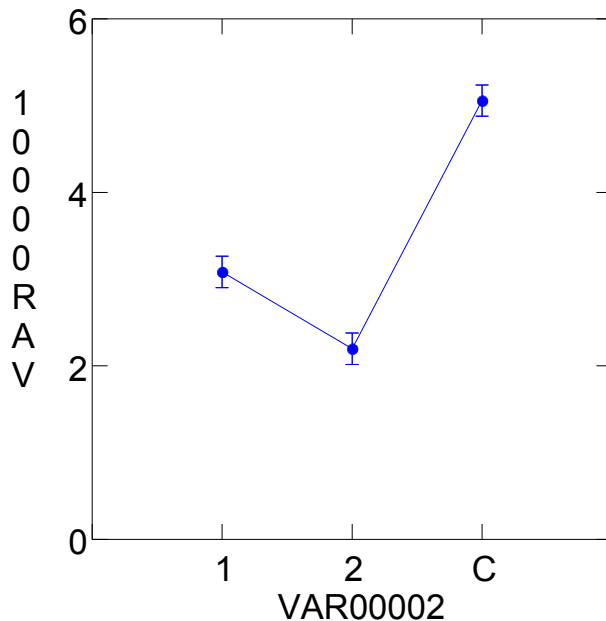

Fescue
alone:
control

Endophyte-free (E-)
knapweed and fescue

The differences in fescue biomass are statistically significant

Least Squares Means

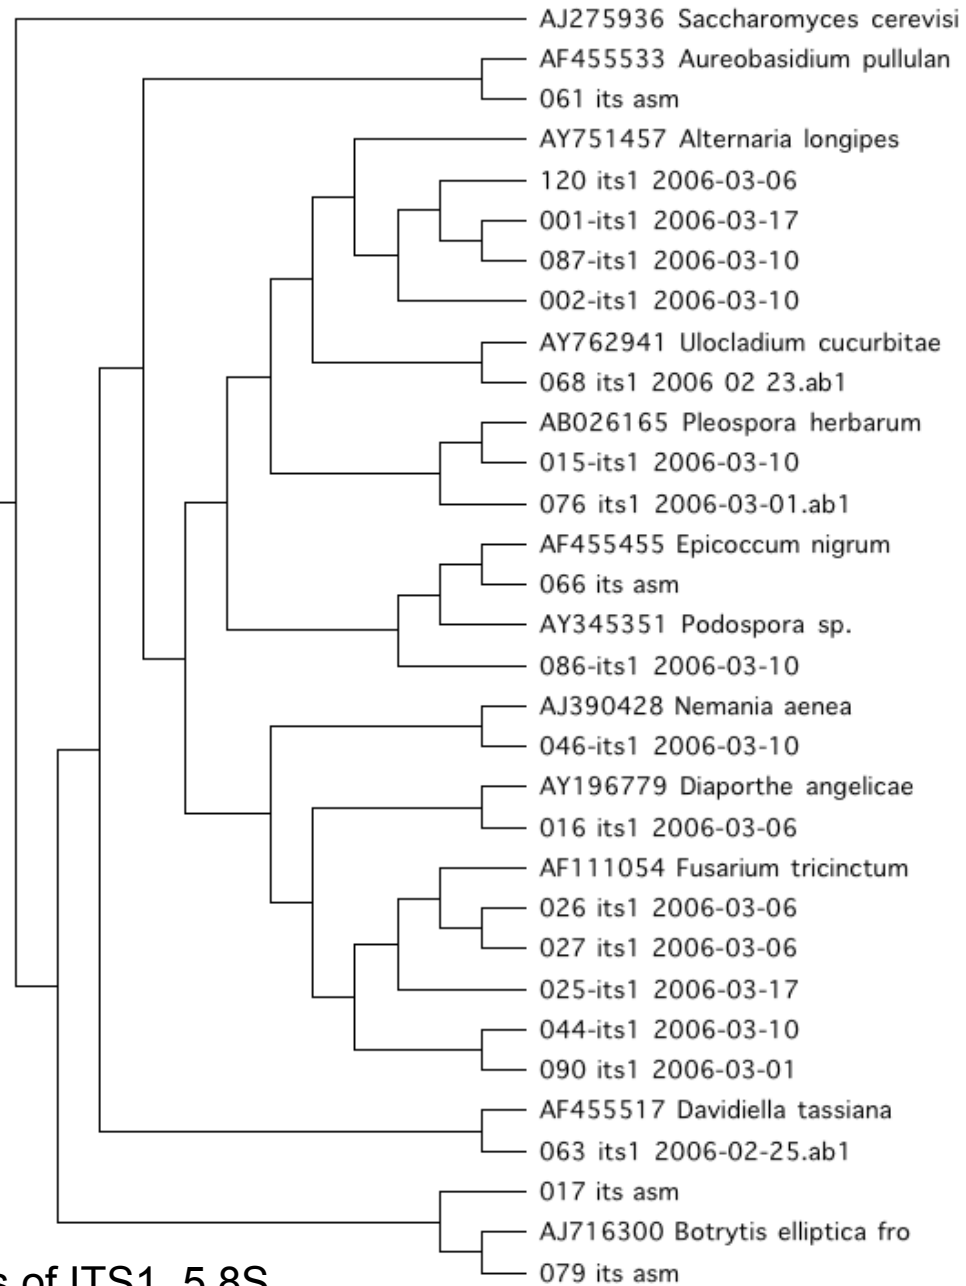

1 E- plants

2 E+ plants

C Control

(*Festuca
idahoensis*
alone)

How diverse are knapweed endophytes?

MP tree from phylogenetic analysis of ITS1, 5.8S
and ITS2 gene sequences

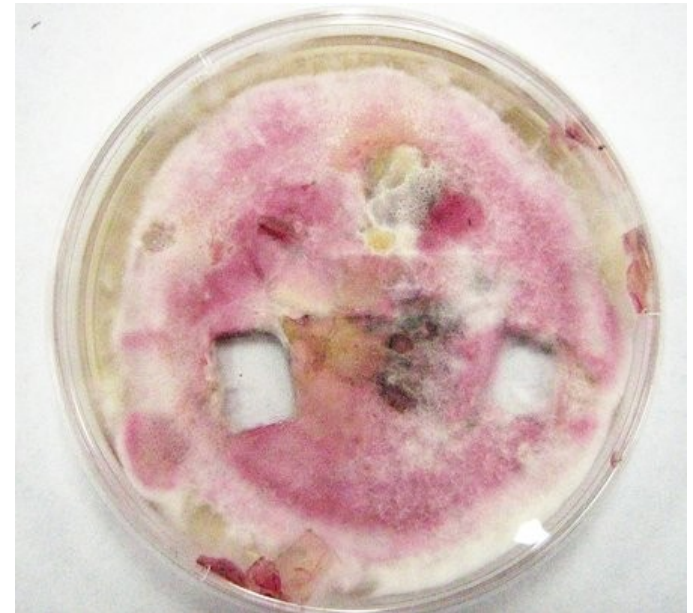

Most frequent ITS haplotypes

Botrytis
spp., 6 ITS
haplotypes

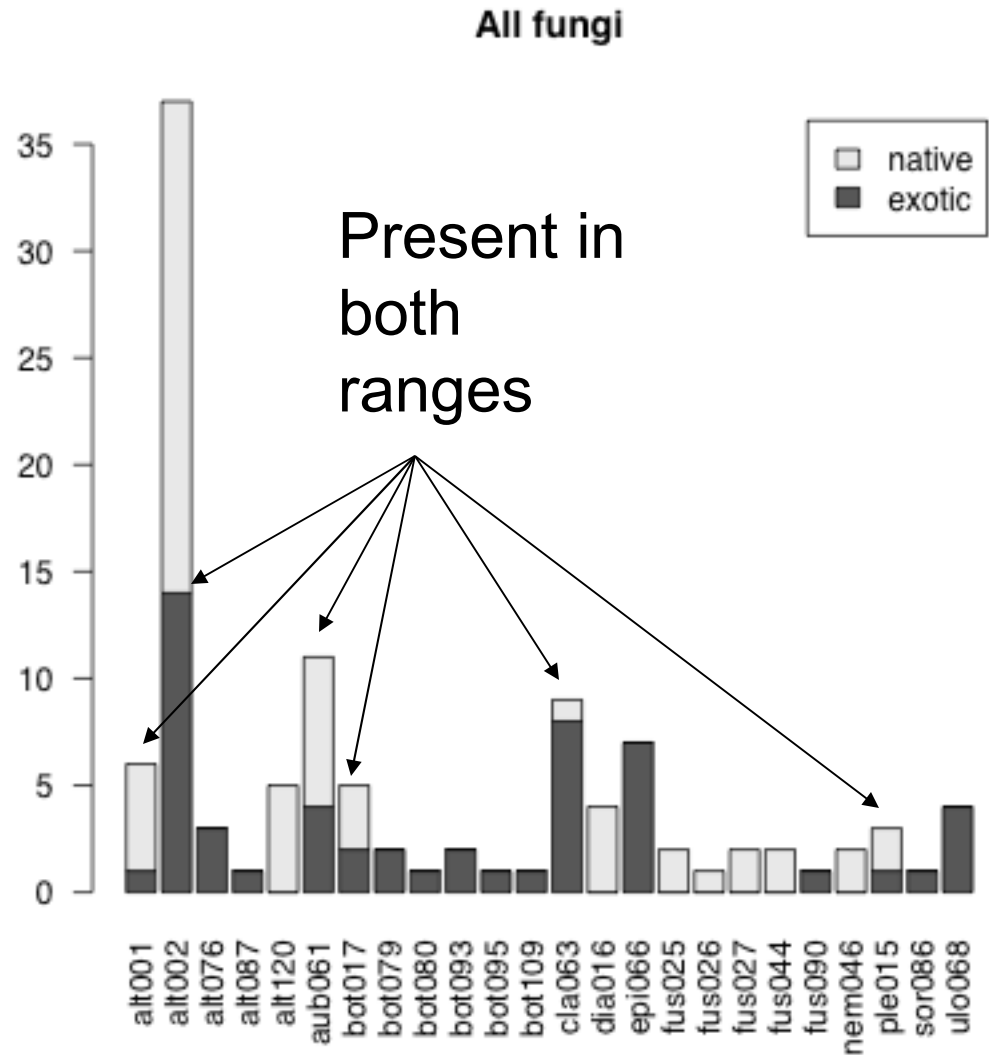

Alternaria
spp., 5

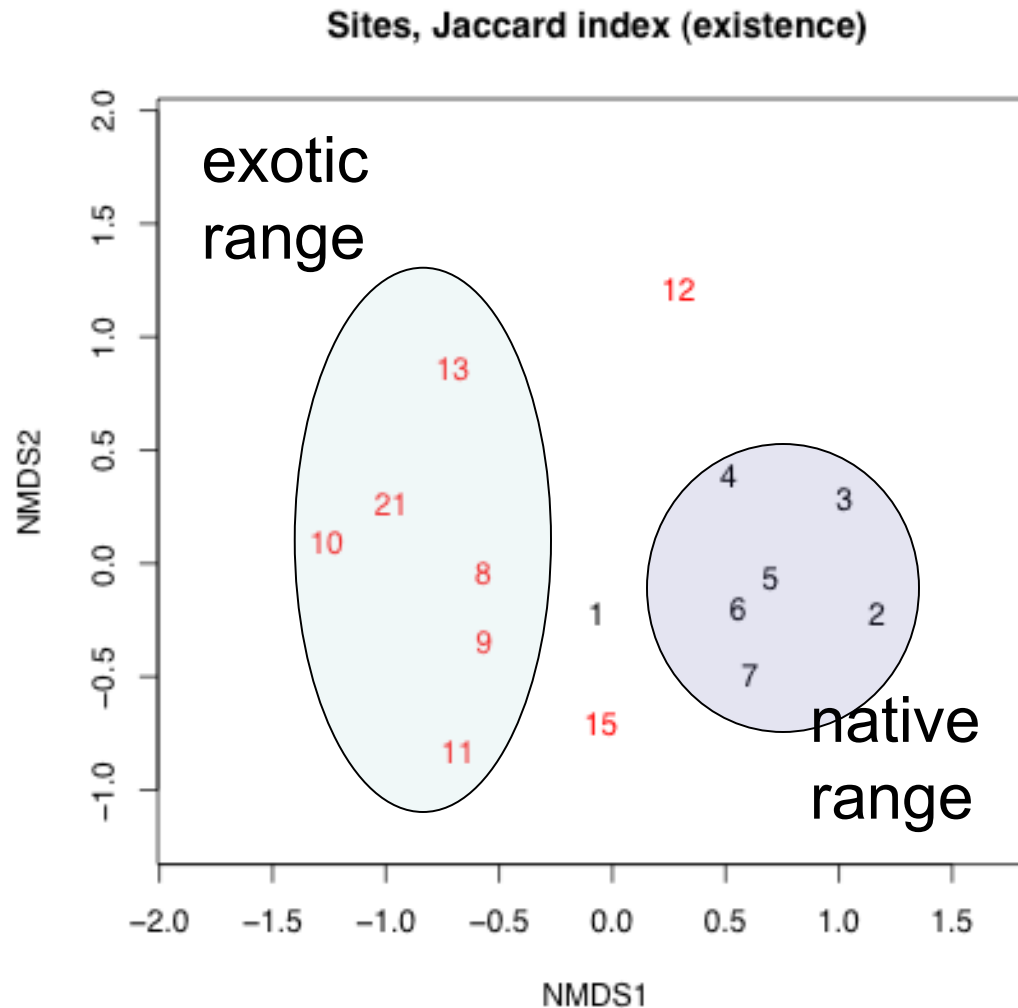

Fusarium
spp., 5 (all
are new
to
GenBank)

Distribution among native and exotic ranges

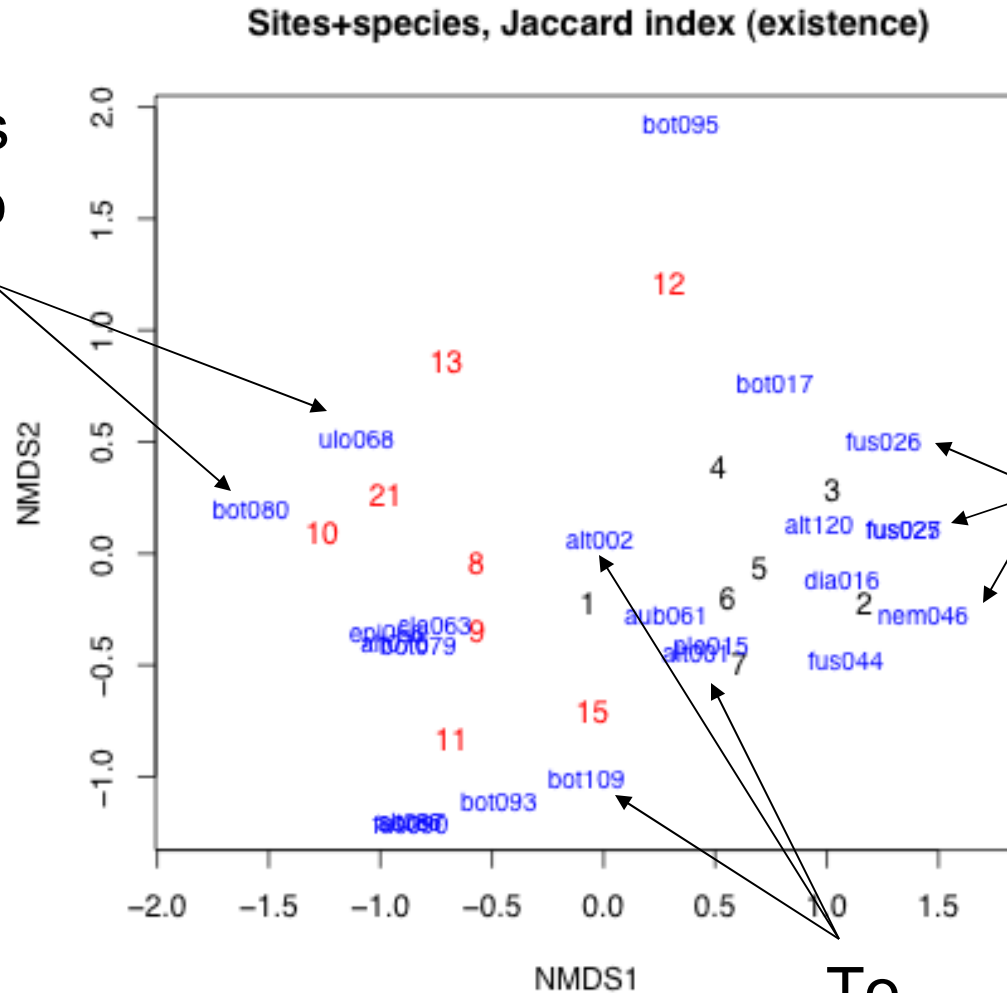

Are endophyte communities different?

Patterns of co-occurrence

Haplotypes
common to
exotic
range

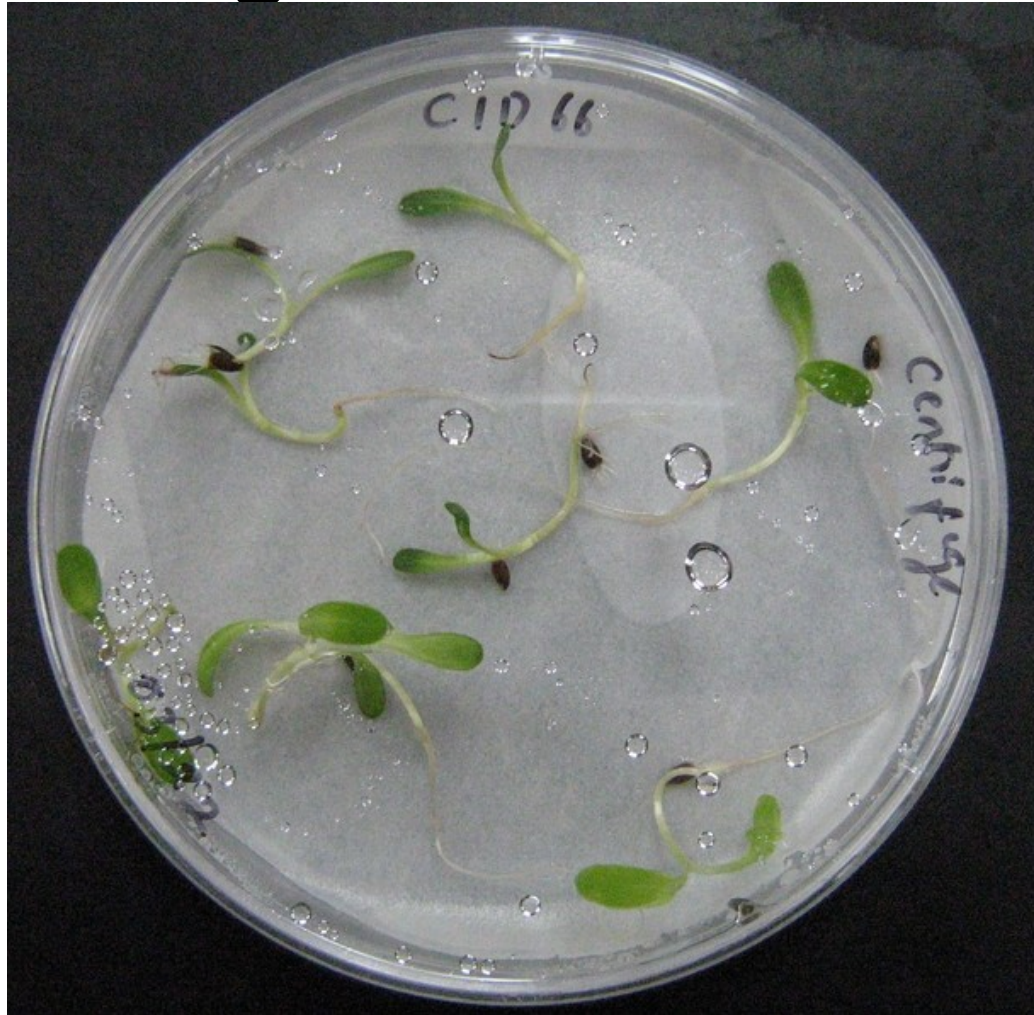

Haplotypes
common to
native
range

To
both

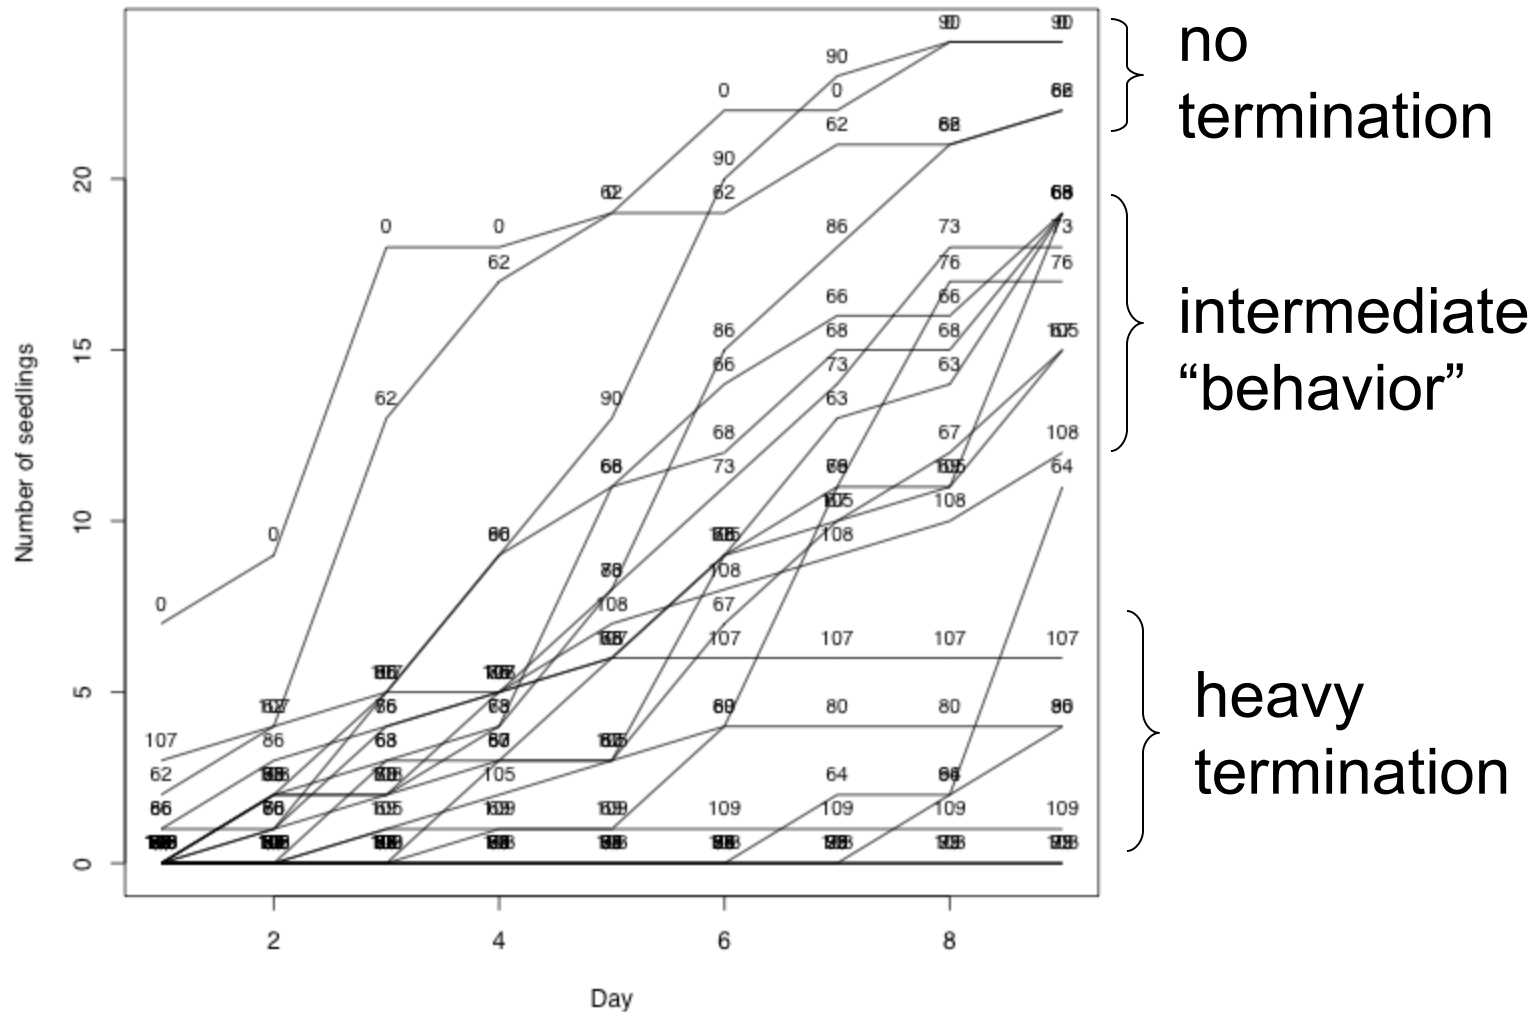

Host-jumping vs. co-introduction

- Endemic or nearly endemic ITS haplotypes;
- Explanation of effect from Callaway et al.;
- Communities form two “clouds” on ordination
- 6 (25%) identical ITS haplotypes from both ranges;
- Eurasian origin of some sequences;
- Some communities are “intermediate” on ordination

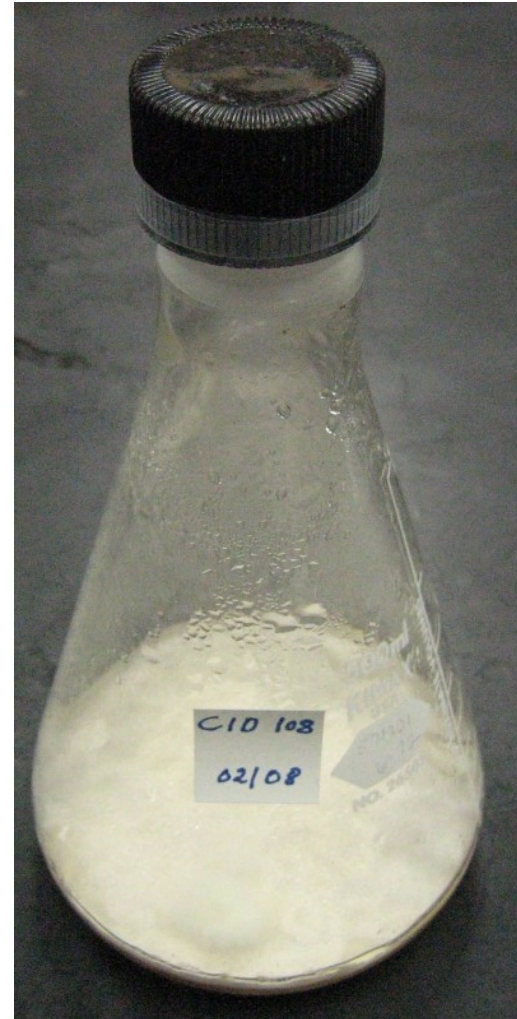

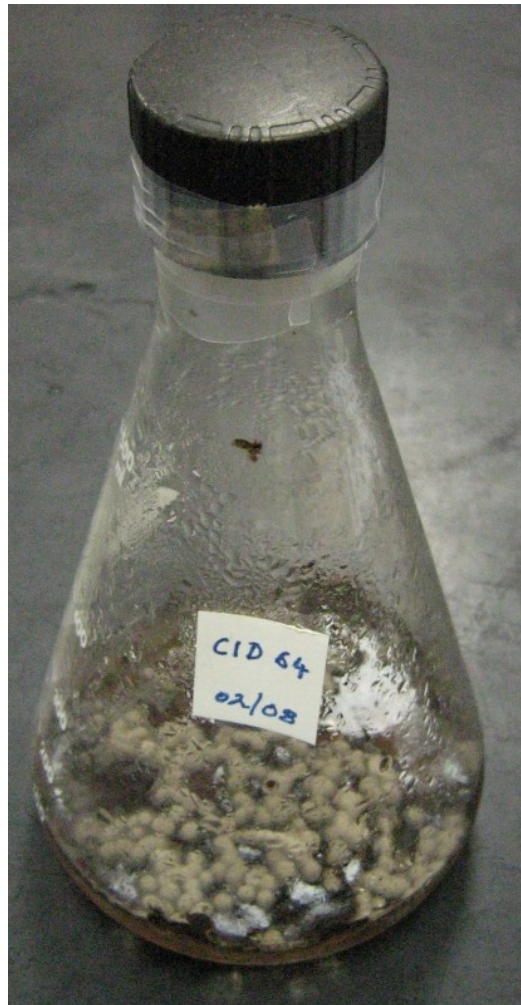

Endophytes and seed germination

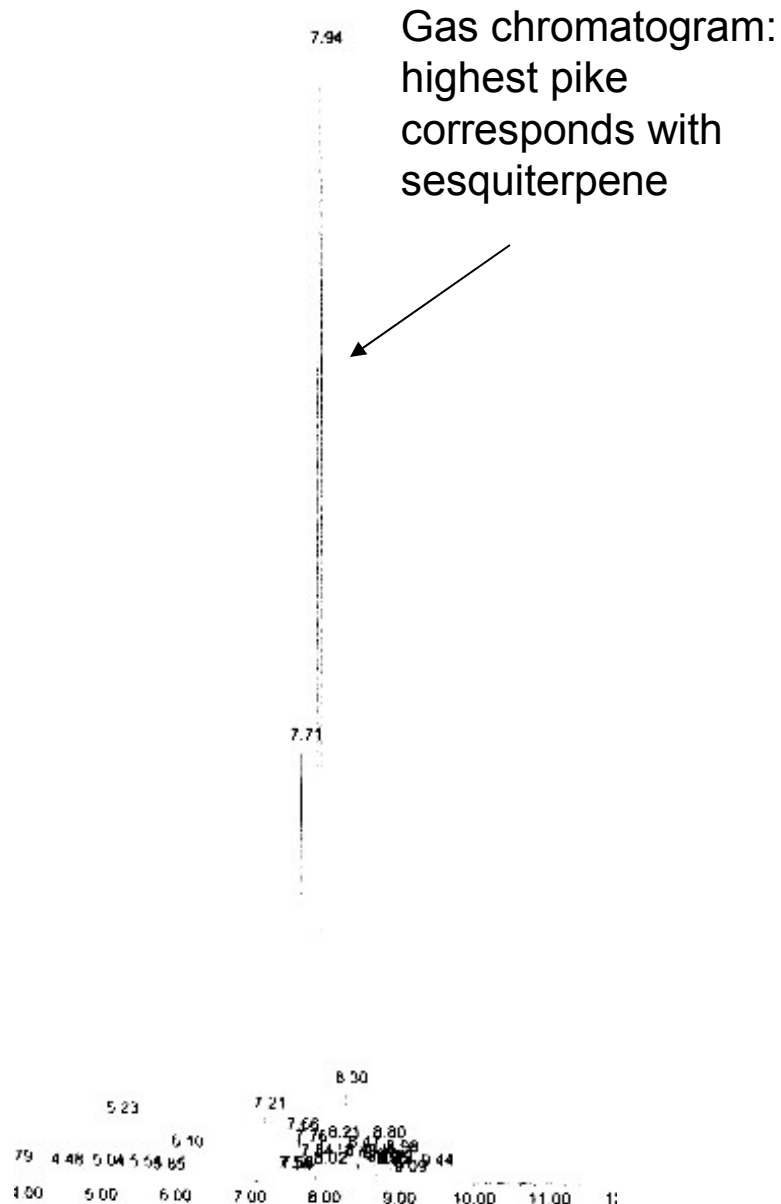

Some endophytes are capable to terminate seed growth

Liquid cultures and volatile compounds

At least some
endophytes
can produce
sesquiterpenes

Conclusions

- There are huge diversity of fungal endophytes in the knapweed (> 24 species), endophyte communities are also different
- The endophytes of knapweed are capable (a) to inhibit the growth of fescue grass, (b) to terminate the germination of seeds, (c) to produce volatile compounds (sesquiterpenes)
