

# Why do Zebras Have Stripes?

Whitney Peterson

**PLAINS ZEBRA**  
**(*Equus quagga*)**

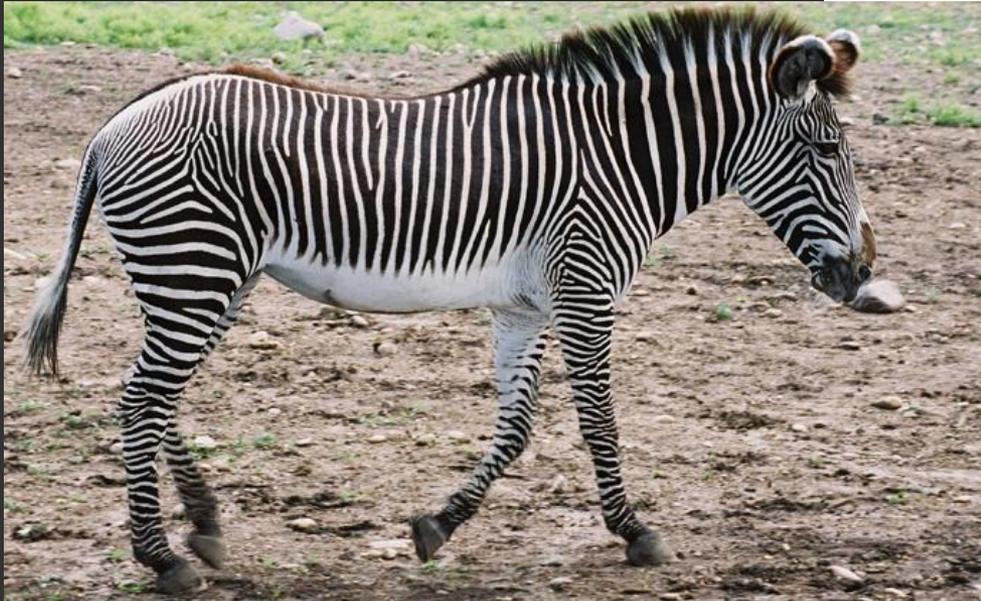

**Mountain Zebra  
(Equus zebra)**

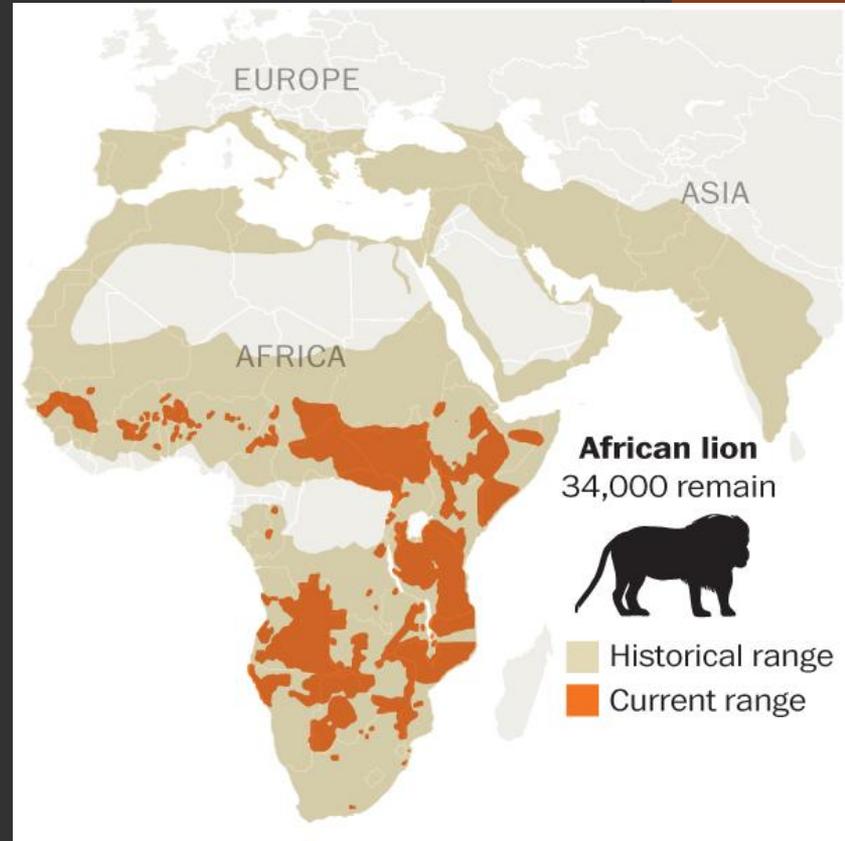

**Grevy's Zebra**  
*(Equus grevyi)*  
**"Imperial Zebra"**

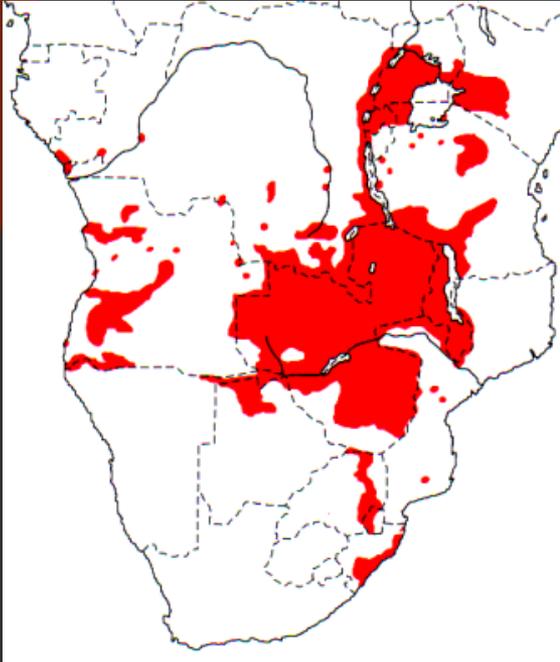

# Hypothesis #1 : Predation Evasion

**based on the idea that stripes are an optical illusion for animals of prey and would confuse them**

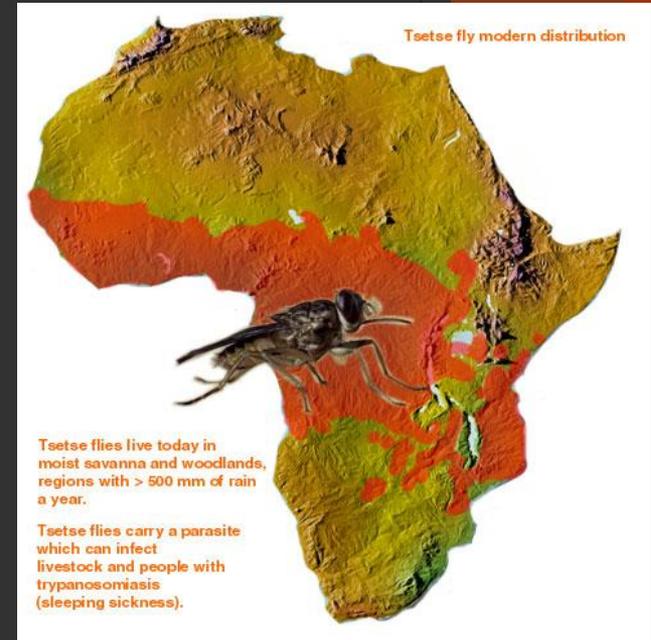

# Hypothesis #2: Biting flies

## Tabanis Fly distribution

## Tsetse Fly Distribution

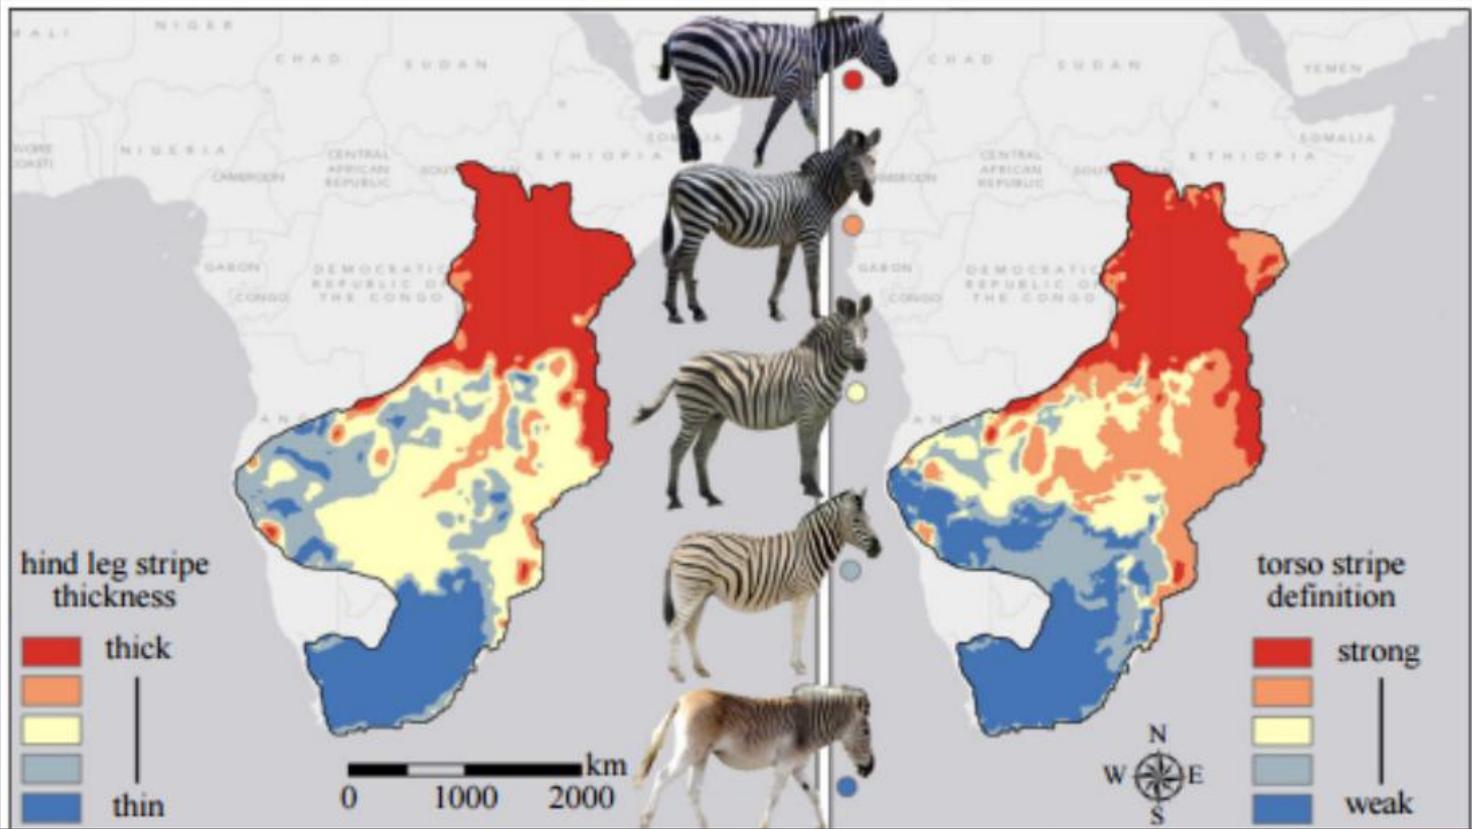

- stripes may break up the silhouette of the body against a strong background, or create an optical illusion that confuses flies
- Tsetse flies and other biting flies can negatively impact animals in a number of ways: both directly, through loss of time spent foraging and energetic expenditures that lead to weight loss, and indirectly, through the transmission of disease

# **Hypothesis #3: Thermoregulation**

**based on the idea that black and white stripes would heat up differentially, thus causing differential airflow between black and white stripes and creating eddies of air that would have a cooling effect**

# Striping Map

# Hypothesis #4: Adaptive drivers of natural selection

- ▶ . The most consistently important variables were:
- ▶ isothermality (BIO3)
- ▶ mean temperature of the coldest quarter (BIO11).
- ▶ Maximum annual vegetation as measured by the Normalized Difference Vegetation Index (NDVIMAX)
- ▶ precipitation of the wettest month (BIO13) were also important for some characteristics.
- ▶ Estimated tsetse fly and lion distributions, by contrast, consistently failed to predict stripe pattern variation

**Table 1.** Random forest models, the percentage of variance they explain and their ability to predict stripe characteristics of zebra at new sites. (Models with significant predictive ability are in bold.)

body part	stripe characteristic	models		predictions	
		model	% variance explained	$r^2$	$p$
